Motivation to learn

Academic performance

### ABSTRACT

Previous studies have shown that teacher messages are related with many school-related outcomes, such as students' engagement and performance. However, it is still unknown how the combination of different elements within teacher messages relate with these outcomes. Based on the message framing theory and the self-determination theory, the present study examined how teachers' engaging messages link to student's motivation to learn and academic performance. A total of 1209 students between grades 8 and 12 drawn from 63 classes participated in the study. Participants completed self-report measures of teachers' engaging messages and motivation to learn. Academic performance was measured using students' grades obtained from school records. Multilevel structural equation models were performed (ML-SEM) to test the hypothesized relations among variables. ML-SEMs results confirmed our hypothesis and showed that teacher engaging messages indirectly predicted student's academic performance via motivation to learn. Specifically, the autonomous forms of motivation to learn positively predicted performance and the controlled forms of motivation to learn where negatively related to performance. The present findings highlight a resource teachers can rely on to motivate students and improve their academic outcomes. These results set the basis for future educational interventions targeting teaching practices.

## ¿Predicen los mensajes del profesorado la motivación para aprender y el rendimiento?

### RESUMEN

Estudios previos han demostrado que los mensajes del profesorado están relacionados con múltiples variables a nivel escolar, entre ellas, la implicación y el rendimiento de los estudiantes. Sin embargo, aún se desconoce cómo la combinación de los distintos elementos de estos mensajes se relaciona con estas variables. Fundamentado en la teoría del enfoque del mensaje y en la teoría de la autodeterminación, el presente estudio analiza cómo los mensajes del profesorado se relacionan con la motivación para aprender de los estudiantes y con su rendimiento académico. En total, 1209 estudiantes entre los cursos de 2° de ESO y 2° de Bachillerato, repartidos en 63 grupos, han participado en el estudio. Los estudiantes han notificado, mediante medidas de autoinforme, sobre los mensajes de su profesorado y su propia motivación para aprender, mientras que el rendimiento académico de los estudiantes se ha obtenido a través de las calificaciones oficiales de sus expedientes académicos. Para comprobar las relaciones esperadas entre las variables se han llevado a cabo varios modelos multinivel de ecuaciones estructurales (ML-SEM). Los resultados de los ML-SEM han confirmado nuestras hipótesis y han mostrado

que los mensajes del profesorado predicen indirectamente el rendimiento académico de los estudiantes mediante la motivación para aprender. En concreto, la motivación autónoma para aprender predice positivamente el rendimiento y la motivación controlada se relaciona negativamente. Estos resultados ponen de relieve un nuevo recurso del que puede hacer uso el profesorado para motivar a sus estudiantes y mejorar sus resultados académicos, sentando las bases para futuras intervenciones educativas dirigidas a mejorar la práctica docente.

## Introduction

“If you work hard you will learn interesting facts”. “Unless you work hard you will get into trouble”. These are examples of messages that teachers use to encourage engagement among their students. If these messages are read carefully, it can be noticed that they support different kinds of motivations (i.e., motivational appeals; [Santana-Monagas et al., 2022](#)), the first is intrinsic to oneself (interest) and the second is external (punishment). It can also be observed that the messages are framed differently: gain-framed messages highlighting positive consequences and loss-framed messages highlighting negative consequences. In educational contexts, different teacher messages (e.g., reprimands, praise, fear appeals, etc.) have shown to be relevant for many student outcomes such as attention capacity, motivation, performance and engagement ([Caldarella et al., 2020](#); [Putwain et al., 2017, 2019](#); [Putwain & Remedios, 2014](#)). However, it could be that teachers can be relying on and integrating different kinds of messages within their speech. Thus, the present work approaches the study of teachers’ engaging messages as a construct derived from the combination of *message framing theory* (MFT: [Rothman & Salovey, 1997](#)), and *self-determination theory* (SDT: [Ryan & Deci, 2000, 2020](#)) and aims to examine how messages integrating motivational appeals and frames (gain vs. loss) relate to students’ motivation to learn and academic performance.

### Message framing theory

Teachers’ engaging messages encompass both the frame and the motivational appeals within it. Regarding the frame, messages can prompt different responses depending on where the emphasis is located ([Rothman & Salovey, 1997](#)). These can highlight the benefits of engaging in an activity (gain-frame) or the cost of not doing so (loss-frame). In educational contexts, teachers can tell their students to study, work hard, and pay attention in class to obtain higher grades (gain-framed message) or they can tell them that if they don’t do so, they will fail their subject (loss-framed message). Both kinds of messages use the same stimuli to promote motivation, but with a different emphasis.

Research following the MFT under educational contexts is scarce, but relevant. Studies following this theory have gathered evidence towards the negative effects that loss-framed messages can have on students ([Putwain et al., 2019](#)). For instance, it has been found that messages that focus on fear of failure, namely loss-framed messages, trigger anxiety among students ([Putwain & Symes, 2011](#)), relate to low behavioural engagement, and worse performance ([Putwain et al., 2017](#)). Thus, given the non-adaptive outcomes such messages can elicit, teachers should be aware of such phenomena. Contrastingly, the possible outcomes related to the use of gain-framed messages remain largely unexamined.

Furthermore, the few studies examining both messages together have not directly measured the use of these by teachers in natural contexts, but instead under artificial settings or under hypothetical contexts. These studies have shown mixed results. For instance, in [Symes and Putwain \(2016\)](#), message frame did not influence message appraisal, whereas, on another study by the

same authors, gain-framed messages were related to a greater likelihood of disregarding the message when subjective task value and expectancy of success were high, compared to loss-framed messages ([Putwain & Symes, 2016](#)). These diverse results along with the lack of knowledge available regarding gain-framed messages underlines a gap in the literature aimed to be addressed with the present study.

### Self-determination theory

Turning to motivational appeals, researchers following a SDT approach ([Ryan & Deci, 2020](#)) have identified four types of motivations that drive students to engage or not in certain activities. Motivational appeals can be defined as messages used by teachers that highlight students’ different motivations for engaging in a task. Motivations are commonly classified into autonomous forms of motivations (i.e., intrinsic and identified) and controlled forms of motivation (i.e., introjected and extrinsic; [Deci & Ryan, 2008](#); [Howard et al., 2021](#)). Autonomous motivation concerns acting with willingness and choice. Contrastingly, controlled forms of motivations concern acting moved by external demands or forces ([Deci & Ryan, 2008](#)). For instance, when teachers appeal to a controlled motivation, students’ behaviour would be driven by rewards or punishments (e.g., doing homework to avoid detention) or by internal sources such as guilt or self-esteem (e.g., studying to make one’s parents feel proud). Moreover, when teachers appeal to autonomous forms of motivation, students engage in an activity purposefully and because they think it is worth it (e.g., working hard because they think it is important to obtain a job in the future) or for the enjoyment they experience when doing so ([Deci & Ryan, 2016](#)). Nevertheless, in certain circumstances students might feel none of these motivations but instead feel completely amotivated, that is, a lack of intention to act ([Behzadnia et al., 2018](#)). Amotivation can result from students feeling a lack of competence, lack of interest or value, or a lack of contingency between a behaviour and its expected outcome ([Deci & Ryan, 2008](#)). It has commonly been identified as a distinctive negative predictor of engagement, learning processes, and well-being ([Ryan & Deci, 2020](#)).

When students are autonomously motivated their performance is enhanced and, they feel fulfilled and content ([Jang et al., 2016](#); [León et al., 2015](#)). For instance, in [Taylor et al.’s \(2014\)](#) meta-analysis, results indicated that autonomous motivations (i.e., intrinsic and identified) were positively related with students’ school achievement, whereas controlled motivations (i.e., introjected and external) related negatively with amotivation having the strongest negative relation with achievement. Moreover, [Froiland and Worrell \(2016\)](#) showed that an intrinsic motivation to learn predicted students’ engagement. Thus, fostering autonomous forms of motivation (e.g., intrinsic or identified) among students would result of great importance given its substantial effect on student outcomes. Ways teachers can promote this type of motivation is through their need-supportive teaching and their instructional practices ([León et al., 2017](#)).

Regarding need-supportive teaching, SDT researchers have examined and described a different set of teaching behaviours that foster one type of motivation or another ([Collie et al., 2019](#);

Message frame	Motivational appeals	Example
Gain-frame	Intrinsic	Gain-framed intrinsic: “If you work hard, you will learn interesting facts.”
	Identified	Gain-framed identified: “If you work hard, you will be prepared for your future studies.”
	Introjected	Gain-framed introjected: “If you work hard, you will feel proud of yourself.”
	Extrinsic	Gain-framed extrinsic: “If you work hard, I’ll give you a reward (star, sticker, etc.).”
Loss-frame	Intrinsic	Loss-framed intrinsic: “Unless you work hard, you will miss the opportunity to understand interesting issues.”
	Identified	Loss-framed identified: “Unless you work hard, you will only be able to get low paid jobs.”
	Introjected	Loss-framed introjected: “Unless you work hard, you will feel ashamed.”
	Extrinsic	Loss-framed extrinsic: “Unless you work hard, you will miss your break.”
Amotivation		Amotivation messages: “It does not matter if you work hard, you will fail anyway.”

Figure 1. Engaging Messages.

Vansteenkiste et al., 2012). Such behaviours support students’ innate basic needs for autonomy (the sense of willingness to actively participate in a certain activity), relatedness (feel truly bonded and connected with others), and competence (interacting effectively with the environment; Vansteenkiste et al., 2020) which result essential for growth and optimal functioning (Ryan & Deci, 2000). Autonomy-supportive teaching practices include offering choice, providing informative feedback, and showing care and attention to students’ concerns, among others (Reeve, 2009). These practices have been related with students’ well-being (Behzadnia, 2020), engagement (Leo et al., 2020), motivation (Haerens et al., 2015), learning and behavior (Vansteenkiste et al., 2012). Among these behaviours, the study of teacher messages has been approached as a way of displaying an informative or controlling language (Legate et al., 2021; León et al., 2017; Reeve, 2009). However, this way of measuring teachers’ communications does not differentiate between different types of motivation that could be communicated in a more or less forceful way. Thus, examining teachers’ engaging messages from the present study perspective, as an approach to motivate students, might help to better understand teaching practices. From a practical point of view, this approach might be beneficial for teachers as it examines the exact messages they can rely on (i.e., “If you work hard, you will learn interesting facts”) instead of referring to a certain language which could seem vague (i.e., “my teacher uses forceful language”; Jang et al., 2016).

Although research under the SDT has originated a strong body of evidence to reflect teacher’s capacity to motivate and engage students (Ryan & Deci, 2020), researchers are still highlighting the continuing decline in students’ academic interest (Lazarides et al., 2019) and intrinsic motivation (Scherrer & Preckel, 2019) throughout adolescence. This fact underpins the importance of the need to persist conducting research on new ways teachers can foster students’ motivation to learn. Teachers, as key agents for students’ learning (León et al., 2015; Ruiz-Alfonso & León, 2017), must be aware of the power they have to motivate students and raise their academic interest. A teacher capable to do so would not only be essential for students’ engagement and academic performance, but it would also have many other beneficial implications, such as need satisfaction, enhanced experiences of well-being (Behzadnia et al., 2018; Liu et al., 2017) and less maladaptive behavior (Oostdam et al., 2019).

#### Self-determination theory and message framing theory

Following Busemeyer’s (2017) and Gigerenzer’s (2017) recommendations, it is essential to not just rely on one macro-theory but also to rely on distinctive theories to accomplish a more accurate approximation to the study of human learning and behaviour. This

approach may serve as a pathway for researchers to advance and gather new insight (Mayer & Sparrowe, 2013) on fields that, a priori, may seem unrelated. The following work relies on both the SDT and the MFT to enhance the study of teachers’ engaging messages as both theories could complement each other as well as counteract their weaknesses. In other words, following both of these theories would allow us to consider what neither theory could separately. For instance, MFT does not examine the types of motivation contained within the message focussing only on its frame, when in fact the motivation could determine students’ outcomes. Likewise, the SDT does not consider the frame of the message when teachers appeal to a certain motivation, despite its implication on student outcomes, as proven previously by researchers (Nicholson et al., 2019; Putwain et al., 2019; Putwain & Remedios, 2014). Together, this synthesis would lead to a better understanding of how each element of teacher messages (i.e., motivational appeals or message frame) contributes to its effect on students. It could help us acknowledge whether a certain frame can diminish or reinforce the effect of a certain motivational appeal and viceversa. Figure 1 displays examples of the different messages that result when relying on both theories.

#### Multilevel approach

Teachers could use the same, or similar, engaging messages with the whole class (e.g., items could ask “My teacher tells *the class* that unless *we* work hard, *we* will miss our break”). Alternatively, they could direct, or adapt, engaging messages to specific students (e.g., items could ask “My teacher tells *me* that unless *I* work hard, *I* will miss my break). The present study used the latter approach to ask students about the teacher messages directed towards them specifically and not the whole class. Our rationale for adopting this approach is that teachers have reported adapting messages to specific students (Flitcroft et al., 2017). For example, a teacher might tend to rely mostly on intrinsic motivational appeals to encourage their students to work hard. However, this same teacher might notice that a certain student works harder when rewarded and hence might rely more on external motivational appeals. In this case, we can obtain two indicators with different meanings: the message the teacher uses with each student and the teacher’s tendency towards a particular message. That is, the most common messages the teacher uses with students in the same class. Thus, we can find data located at different levels, Level 1 data (L1 or student-level) refers to messages directed to specific students and Level 2 data (L2 or teacher-level) refers to the teacher’s tendency (Stapleton et al., 2016). When considering the multilevel nature of the data, researchers can approach a more thorough understanding of the effect these messages have on students.

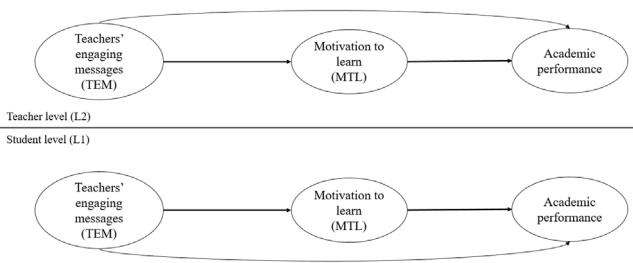

Figure 2. Proposed ML-SEM.

### The present study

The aim of the present study was to examine, relying on the SDT and the MFT, how teacher engaging messages relate with students' motivation to learn and academic performance. Based on the aforementioned studies showing that negative outcomes related to loss-framed messages and positive outcomes related to autonomous forms of motivation (Froiland & Worrell, 2016; Nicholson et al., 2019; Putwain et al., 2019; Taylor et al., 2014), the following hypothesis were reached: students' perceptions of teacher's engaging messages characterized by a gain-frame and by autonomous motivational appeals will relate positively with students' autonomous motivation to learn, whereas students' perceptions of teacher's amotivation messages will relate positively with amotivation among students (H1). Autonomous motivation to learn among students would positively relate with their academic performance, whereas amotivation will negatively relate with their academic performance (H2). Finally, it is expected that students' perceptions of teacher's engaging messages relate indirectly with students' academic performance via motivation to learn (H3) (see Figure 2).

### Method

#### Participants

The sample of the present study comprised 1209 students (600 females, 591 males, and 18 not reported; *Mean age* = 15.86, *SD* = 1.45) between grades 8-12. In total 49 teachers were evaluated (29 females, 19 males; *Mean age* = 46.38, *SD* = 8.07) by their corresponding students that were drawn from 63 classes from ten different secondary schools on the island of Gran Canaria (Spain) from both rural and urban environments. Students came mostly from middle-class families. The sampled schools presented no potential ethnic differences as most of the students were from the Canary Islands.

#### Measures

##### Teachers' engaging messages

In the absence of an existing instrument, new items were developed to measure teachers' engaging messages. This new instrument is based on the *Teachers Use of Fear Appeals Questionnaire* (TUFAQ; Putwain et al., 2019) and incorporates new items framed by SDT and MFT to examine a wider variety of teacher messages. The instrument is composed of a total of 36 items preceded by the stem "My teacher tells me that. . .". Items were grouped into nine factors. Eight of the factors corresponded to the four types of self-determined motivation (*intrinsic*, *identified*, *introjected*, and *external*) and its frame (*gain* vs. *loss*). The ninth factor was *amotivation* which was not classified by frame as it completely lacked one. Example items are displayed in Figure 1. Factors showed a high internal consistency with only gain-framed external showing

a moderate reliability (see Table 1). Different multilevel confirmatory factor analyses (CFAs) were run to compare the hypothesized model against plausible alternates. The hypothesized model displayed better fit indices than the plausible alternates considering the frame and motivational appeals independently (see supplementary material). Items were rated according to a seven-point Likert scale (1 = does not correspond at all to me to 7 = fully corresponds to me). Model fit indices for the CFA were as follows:  $\chi^2(1143) = 1873.427$ ,  $p < .001$ , RMSEA = .028, CFI = .971, TLI = 968, SRMR<sub>W</sub> = .049, SRMR<sub>B</sub> = .138.

##### Motivation to learn

Motivation to learn was measured using five of the seven subscales of the Spanish version of the *Échelle de Motivation en Éducation* (Núñez et al., 2005). Each subscale was composed of 4 items preceded by the stem "Why do you study?". The subscales used were: *amotivation*, *external motivation*, *introjected motivation*, *identified motivation* and the subscale of *intrinsic motivation* (see supplementary material for example items). Similar to prior studies (León et al., 2015), factors displayed a high internal consistency (see Table 1). Items were rated according to a seven-point Likert scale (1 = does not correspond at all to me to 7 = fully corresponds to me). Model fit indices for the CFA were as follows:  $\chi^2(120) = 12195.584$ ,  $p < .001$ , RMSEA = .056, CFI = .900, TLI = .881, SRMR<sub>W</sub> = .056, SRMR<sub>B</sub> = .409.

##### Academic performance

Students' academic performance was measured using teacher-estimated grades in maths, obtained from official school records. Grades ranged between 0-10, being 10 the highest possible mark. In the Spanish education system grades are assigned by teachers according to different rubrics provided by the government. These grades are of great importance as they define the universities and degrees students can have access to.

##### Procedure

We first contacted the different schools and requested their collaboration. Questionnaires were administered individually by researchers during a teaching period where participants' assessed teacher was not present. Items were made specific to one compulsory subject, namely mathematics. For engaging messages, students were asked to think about their current mathematics teacher. The objectives of the research were explained to participants, emphasizing the voluntary and confidential nature of their participation. All participants provided informed consent to participate. The study was conducted in accordance with the ethical guidelines of the Declaration of Helsinki and was approved by the University Human Research Ethics Committee.

##### Data analysis

As mentioned, when following a multilevel approach, students' ratings can be aggregated to serve as a measure of teachers' tendency. Similar answers among students would indicate that what is been measure is, in fact, teacher's messages and not students' impressions (Marsh et al., 2012). Researchers can rely on ICC statistic, which represents the proportion of variance in the data attributable to the class level, to inform about the similarity observed across students' ratings in a same class (Lüdtke et al., 2009; Marsh et al., 2012). For variables in which students rate a characteristic of the teacher, these values are found typically between .10 and .30, whereas for variables that are specific to each student these values are larger (Marsh et al., 2008). Then, to examine if teacher's engaging messages predict students' motivation to learn and performance, nine multilevel structural equation models

**Figure 3.** Example of one of the nine ML-SEM.

(ML-SEMs; one for each kind of engaging message) were estimated. This approach allows to identify the total effect that a single message has on a student, instead of freely estimating all possible correlations among all constructs (Arens & Morin, 2016). The fit indices used to compare the models and the CFA of the instruments were the following: the root mean square error of approximation (RMSEA), standardized root mean square residual (SRMR), comparative fit index (CFI) and the Tucker–Lewis index (TLI). To the best of our knowledge, there are no current guidelines to interpret multilevel models, therefore, Hu and Bentler's (1999) guidelines for single level models were followed. Models show a good fit when they meet the following criteria: RMSEA < .05, SRMR < .08, and CFI and TLI > .95. However, when working with naturalistic data these indices should be interpreted with some flexibility (Heene et al., 2011). To analyse internal consistency, McDonald's  $\omega$ , Cronbach's  $\alpha$ , the averaged variance extracted, and the composite reliability of all factors were estimated for each of the nine factors proposed (see Table 1). Values  $\geq .7$  are indicators of good reliability (Gu et al., 2017). Messages were modelled with the matching motivation to learn (see Fig. 3 for an example). Separate models for engaging messages were run to keep models as parsimonious as possible (Hox & McNeish, 2020). Including all messages in a single model would add unnecessary complexity resulting in possible non-convergence and requiring a larger sample size and number of clusters (Lüdtke et al., 2008, 2009; Marsh et al., 2009). Moreover, factor loadings were also made constant across levels (Morin et al., 2014). L2 variables were built from the class aggregation of student responses and L1 variables were class-mean centred (Marsh et al., 2012; Morin et al., 2014).

To test whether teacher's engaging messages had a direct or indirect relation with student performance, fully and partially indirect ML-SEMs were tested and compared. For the fully indirect model, relations between variables followed the paths shown in Figure 2, whereas the partially indirect model included an additional direct path between teacher's engaging messages and students' academic performance. To estimate the standard errors

of the indirect paths, the delta method was followed (MacKinnon et al., 2002). This method divides the difference between the simple and the partial correlation by the estimated standard errors and contrasts the result with the standard normal distribution to examine whether there is any interceding variable effect. 95% confidence intervals (CIs) were estimated around the point estimate of the standardised indirect path coefficient. CIs that do not cross zero are statistically significant at  $p < .05$ .

The weighted least square mean adjusted estimator (WLSM) was used as the estimation method due to the categorical nature of the variables and its higher accuracy over the maximum likelihood method especially in cases when categorical variables are not normally distributed (Schmitt, 2011; see Table 1). All data analysis was performed with Mplus 8.4 (Muthén & Muthén, 2021). Missing data were handled with the full information maximum likelihood approach.

## Results

### Descriptive statistics

Descriptive analyses, intra-class correlations, McDonald's  $\omega$ , Cronbach's  $\alpha$ , the averaged variance extracted, and the composite reliability are displayed in Table 1. ICC values show that a moderate proportion of the variability observed was attributed to the differences between classrooms (ICCs .021 to .189).

### Bivariate correlations

Bivariate correlations are displayed in Table 2. Gain and loss-framed messages were positively inter-correlated. Gain-framed messages showed negative correlations with *amotivation* messages and loss-framed messages positive correlations. Broadly, at L1, gain-framed messages and loss-framed messages correlated positively with motivation. *Gain-framed intrinsic* messages were positively correlated with grades, as well as *intrinsic* and *identified motivation*. Finally, at L1, *amotivation* messages and *amotivation* were negatively correlated with grades.

### Multilevel structural equation models

Fully indirect ML-SEMs showed model fit indices that were either comparable to, or superior to the partially indirect models (see Table 3). Given the greater parsimony of the fully indirect ML-SEMs and that, for the partially indirect ML-SEMs direct relations from teacher engaging messages and performance only reached statistical significance ( $p < .05$ ) once (at L2 in the loss-framed iden-

Amotivation	108.988 (1208, 62)	.025	.998	.998	.040	.105

Note. G = Gain-framed; L = Loss-framed;  $\chi^2$  of all models was  $p < .05$ .

tified model;  $p = .033$ ), fully indirect models were retained (fit indices for the partially models can be found in the supplementary material).

#### Direct relations

Table 4 shows the direct relations in the ML-SEMs (unstandardized parameters can be found in the supplementary material). Concerning path 1, mostly all engaging messages related significantly with their matching motivation to learn at both levels of analysis. Exceptions include *gain* and *loss-framed identified*; and *loss-framed intrinsic* messages at L2. When comparing the effects among the different teacher messages, it can be appreciated that among the messages that appealed to autonomous motivations (i.e., intrinsic and identified), stronger relations with motivation to learn were found among gain-framed messages.

Regarding relations on path 2, overall, autonomous motivations to learn positively predicted academic performance at both levels of analysis, whereas controlled motivations to learn (i.e., introjected and extrinsic) negatively predicted academic performance at L2. At L1 *extrinsic motivation* to learn had a very small positive effect on performance. Finally, *amotivation* messages positively predicted *amotivation* to learn, and this in turn, negatively predicted academic performance at both levels of analysis.

#### Indirect relations

Table 5 shows the indirect relations in the ML-SEMs. Overall, the autonomous motivations predicted academic performance at both levels of analysis except for *loss-framed identified* messages, which negatively predicted performance at L2. Indirect relations between introjected messages and performance were never statistically significant at both levels of analysis ( $p > .05$ ). At L2, extrinsic messages (gain and loss-framed) negatively predicted performance, whereas

at L1 its relation with performance was positive, although this effect was small. Lastly, negative indirect relations at L1 and L2 were shown for *amotivation* messages and performance.

#### Discussion

Following a multilevel approach, the present study relies on the SDT and MFT to examine how engaging messages from teachers predict students' motivation to learn and academic performance. Overall, teacher's messages predict students' motivation to learn, and this, in turn, predicts students' performance. Major findings are discussed below.

Regarding H1, as expected, gain-framed messages and autonomous motivational appeals are associated with students' autonomous motivation to learn, whereas amotivation messages predict students' amotivation to study. These findings are consistent with previous studies which have shown how teacher's motivational approach is related to students' motivation and engagement (Collie et al., 2019; Vansteenkiste et al., 2012). Moreover, they also add to this well-established relationship (Deci & Ryan, 2016; Jang et al., 2016; León et al., 2018) by not addressing teacher's motivational approach as a mixture of many different teaching practices (Collie et al., 2019; Reeve & Cheon, 2016) but instead focuses on a specific one (i.e. teachers' engaging messages) to precisely measure its unique effect on students. In such way, the present results strengthen the idea of the power teachers have to motivate students, and engage them in school tasks, but also the ability they have to demotivate them. In this sense, students whose teacher relies on gain-framed messages and autonomous motivational appeals might feel more supported, believing their teacher really wants the best for them. This might make students feel autonomous motivated, which would move them to engage in school-related tasks.

	L1	-.04	.01	-.05, -.03

Note. TEM = Teachers' engaging messages; MTL = Motivation to learn; G = Gain-framed; L = Loss-framed; L2 = Teacher level; L1 = Student level.

An additional finding shows that, at a student level, when comparing both frames, gain-framed messages show stronger relations with student motivation ( $\beta$ s = .269 to .496) compared to those of loss-framed messages ( $\beta$ s = .091 to .377; see Table 5). This implies that highlighting the benefits of a certain activity stimulates students more than emphasizing and appealing to loss. As teachers' engaging messages encompass both the frame and the motivation appeals, this finding suggests that self-determined motivational appeals are more effective when they are accompanied by a gain-frame. These results are the first to highlight the differences between the effect the message frame can have on students and complements the findings of previous works which have shown how loss-framed messages are associated with controlled motivations and lower engagement (Putwain et al., 2019; Putwain & Remedios, 2014). In this sense, results suggest that students might feel more motivated to focus on the positive outcomes they can obtain if they work hard than to focus on the threat or the possibility of losing something they might not even value or that they already have.

Regarding H2, findings show that autonomous forms of motivation (i.e., intrinsic and identified) are positively associated with students' academic performance, and that as expected, amotivation inversely predicts students' academic performance. These results align with the assumptions of the SDT (Deci & Ryan, 2016; Ryan & Deci, 2000) and with previous studies that have identified the relation between autonomous motivation and positive academic outcomes (León et al., 2015; Ruiz-Alfonso & León, 2017). Students who are autonomous motivated will engage in school-related tasks because they enjoy and value them. Their engagement would in turn, influence positively their grades. Instead, amotivated students would have no reason to engage in a certain activity at all, resulting in poor performance (Cheon & Reeve, 2015).

Finally, our results further confirm that teachers' engaging messages are indirectly related to students' academic performance (H3). This finding is key to understanding how teacher messages relate with students' motivation and academic performance as fundamentally different interpretations can derive from paths being direct or indirect. If teacher's engaging messages had a direct effect

on performance, then these would be directly responsible for students' performance. In contrast, results indicate that the messages relate indirectly with student performance via motivation to learn. This knowledge has practical implications for teachers as it articulates a new resource they can rely on to motivate their students and that result in a better academic performance. If teachers could simply rely more on gain-framed messages and those appealing to autonomous forms of motivation, it is likely for them to observe improvements among their students' motivation and performance. Given the novelty of this result, this finding cannot be compared with others.

#### Limitations and future directions

Teachers' engaging messages are addressed by self-reports. To overcome possible sources of unreliability future research should complement the data obtained with the scale with teacher self-reports and observational techniques. Second, our study is cross-sectional. Therefore, no casual relations can be drawn from the present study. Future research should endeavour to conduct longitudinal studies to establish directionality between the present study variables. Third, although teacher grades are better predictors than test scores (Galla et al., 2019) and despite their great relevance to predict several outcomes, such as standardized test scores (Duckworth et al., 2012); and lifetime educational attainment (French et al., 2015); these could seem subjective (Cross & Frary, 1999). Thus, future research could rely on test scores to obtain a more objective measure. Moreover, the present study conducted nine ML-SEM models given their greater parsimony with the available sample. Future research should explore the relations on the present study conducting one ML-SEM. To do so, larger samples are required. Additionally, as previous research has highlighted the effect that the tone of voice might have on students' motivation (Weinstein et al., 2018, 2019), future research could examine how the tone of voice influences the effect teacher engaging messages might have. Furthermore, future studies replicating the present one are needed to examine the reliability and factor loading of certain items and dimensions. To conclude, it could be interesting for future research to examine the predictive value that grades can have on students' motivational experiences, as these could result from the actual fact of grading students (Krijgsman et al., 2017). Similar to previous studies (Liu et al., 2017), it would be of interest to further examine both positive (i.e., well-being) and negative (i.e., ill-being) student outcomes in regard with teachers' engaging messages to further expand on how this teaching practice relate with student's functioning.

#### Practical implications

Considering the impact that teacher engaging messages can have on student's outcomes, the above results may be of relevance for school staff, such as teachers and school psychologists, to tackle one of the main challenges they face: students lack of interest and engagement (Lazarides et al., 2019). As previous researchers have highlighted (Putwain & Remedios, 2014) most teachers are unconcerned about the type of messages they use during their lessons and, may be unaware of the effects they might trigger among students (Flitcroft et al., 2017). A way to tackle this problem could be setting up school-based interventions to instruct teachers about the different engaging messages and their effect. To start, the scale developed for the present study could be used to help teachers recognize their engaging messages and, if it proceeds, show them how they could improve it. Given the negative effects some kinds of messages might prompt (Putwain & Symes, 2011), it might be advantageous to advise teachers of what exact messages they could rely on. For example, based on the current study findings, a way

math teachers can enhance autonomous forms of motivation and reduce controlled forms of motivations and amotivation among students, is relying on gain-framed messages such as "It's all about playing with algebra, if you play applying the logical rules, everything flows and works out fine". This kind of intervention could be very easily implemented in schools as it is simple, inexpensive, and does not require much time.

#### Conclusions

The present study conceptualizes a new resource that teachers can rely on to face amotivation among students. A major conclusion can derive from the present results: teachers' engaging messages predict students' motivation to learn and this, in turn, predicts their academic performance. Specifically, gain-framed and autonomous motivational appeals messages predicted students' autonomous motivation, and this, in turn, positively predicted performance. Contrastingly, amotivation messages predicted students' amotivation to study, and these where negatively related to performance. Therefore, both the frame and the motivational appeals should be taken into account when trying to encourage students to participate in school-related activities. Given the ability teachers have to motivate students and the great influence they exert on them (Caldarella et al., 2020; Jang et al., 2016) these findings could help teachers find new ways to keep doing so.

#### Funding

This study was supported by a grant with reference PID2019-106948RA-I00/AEI/10.13039/501100011033 to Jaime León and by a grant to Elisa Santana-Monagas of the Ministry of Economy, Industry, Trade and Knowledge and the cofinancing of the European Social Fund through the consecution of the predoctoral training programme for research staff in the Canary Islands.
