ABSTRACT

Oxygen and carbon isotope compositions of fossil bird eggshell calcite ($\delta^{18}\text{O}_{\text{calc}}$ and $\delta^{13}\text{C}_{\text{calc}}$) are regularly used to reconstruct paleoenvironmental conditions. However, the interpretation of $\delta^{18}\text{O}_{\text{calc}}$ values of fossil eggshells has been limited to qualitative variations in local climatic conditions as oxygen isotope fractionations between calcite, body fluids, and drinking water have not been determined yet. For this purpose, eggshell, albumen water, and drinking water of extant birds have been analyzed for their oxygen and carbon isotope compositions. Relative enrichments in ^{18}O relative to 16O between body fluids and drinking water of $+1.6 \pm 0.9\text{‰}$ for semi-aquatic birds and of $+4.4 \pm 1.9\text{‰}$ for terrestrial birds are observed. Surprisingly, no significant dependence to body temperature on the oxygen isotope fractionation between eggshell calcite and body fluids is observed, suggesting that bird eggshells precipitate out of equilibrium. Two empirical equations relating the $\delta^{18}\text{O}_{\text{calc}}$ value of eggshell calcite to the $\delta^{18}\text{O}_{\text{W}}$ value of ingested water have been established for terrestrial and semi-aquatic birds. These equations have been applied to fossil eggshells from Lanzarote in order to infer the ecologies of the Pleistocene marine bird *Puffinus* sp. and of the enigmatic giant birds

from the Pliocene. Both $\delta^{13}\text{C}_{\text{calc}}$ and $\delta^{18}\text{O}_{\text{calc}}$ values of *Puffinus* eggshells point to a semiaquatic marine bird ingesting mostly seawater, whereas low $\delta^{13}\text{C}_{\text{calc}}$ and high $\delta^{18}\text{O}_{\text{calc}}$ values of eggshells from the Pliocene giant bird suggest a terrestrial lifestyle. This set of equations can help to quantitatively estimate the origin of waters ingested by extinct birds as well as to infer either local environmental or climatic conditions.
